# Memory Management

## 1. Main memory

Every process that has to execute on the CPU needs a certain amount of memory. Memory management deals with the allocation of requested memory to each process for its execution. It is required in an operating system because the size of the main memory is limited, but the number of processes that a computer can execute is not. Therefore, OS should make sure memory is allocated efficiently, and memory wastage is minimum.

As a process enters the system, they are put into an input queue. The OS takes into account the memory requirements of each processes and the amount of available memory. When a process is allocated space, it is loaded into memory and it can then compete for CPU time. When a process terminates, it releases its memory, which the OS may then fill with another process from the input queue.

According to Chapter 8 - Main memory, main memory is thought of a continuous array of locations. There are two ways we can utilize this continuous memory to accommodate for processes are fixed-size partition or MFT and variable size partition or MVT. Each partition has their own First Fit, Best Fit and Worst Fit.

Please visit Wiki page in the “Memory Allocation” to read more about the two partitions’ advantages and disadvantages

**Users are able to choose Main Memory size, Input Queue Size, and the kind of Fit they want.**

Below is some examples how MFT and MVT of this project work

## MFT

Multiprogramming With Fixed Number of Tasks

Please Enter the following data

Total Memory:

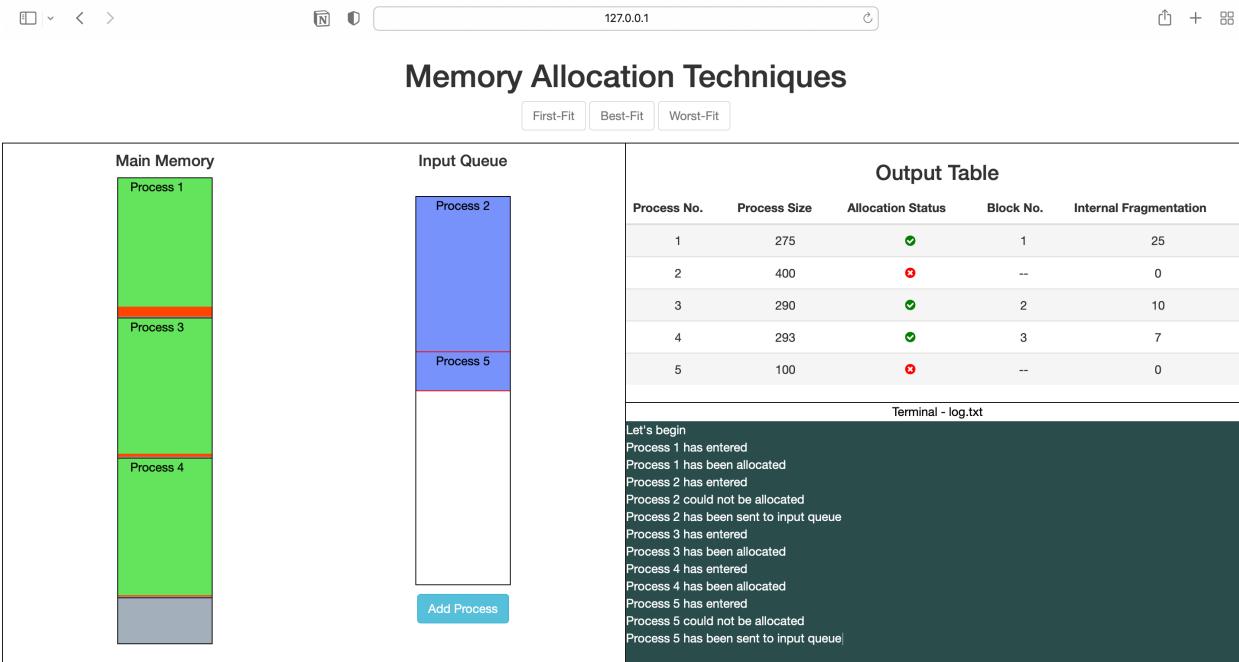

No. of Blocks:

Enter the following block sizes:

Block 1:

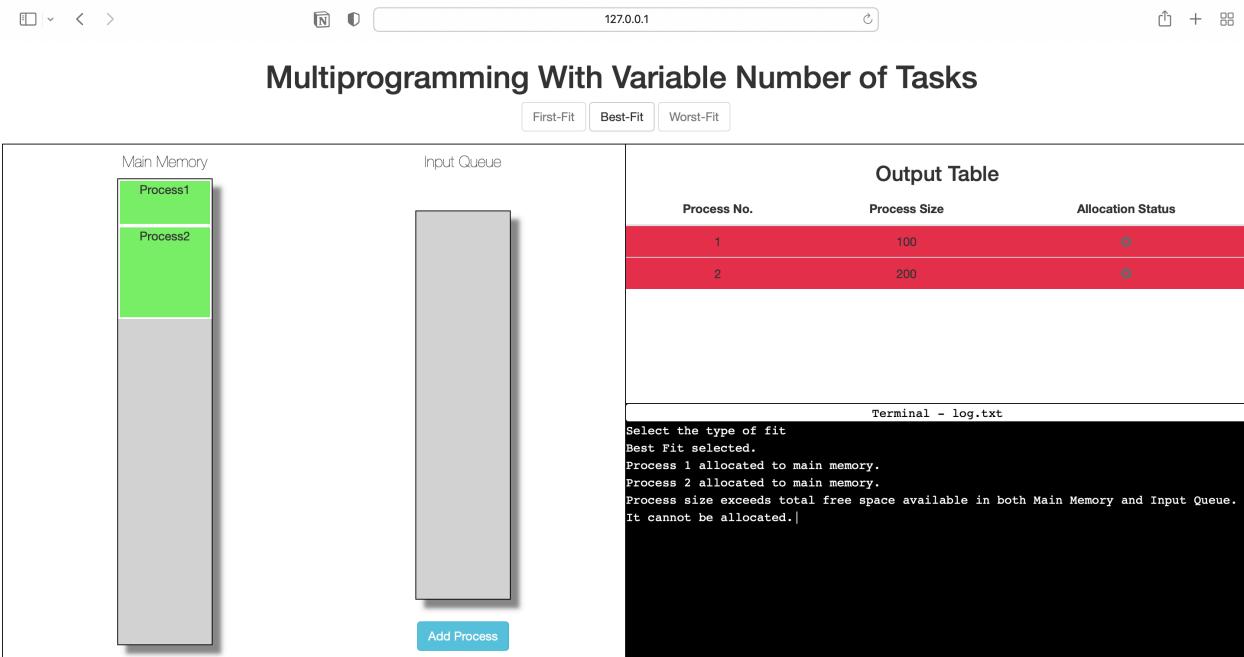

Block 2:

Block 3:

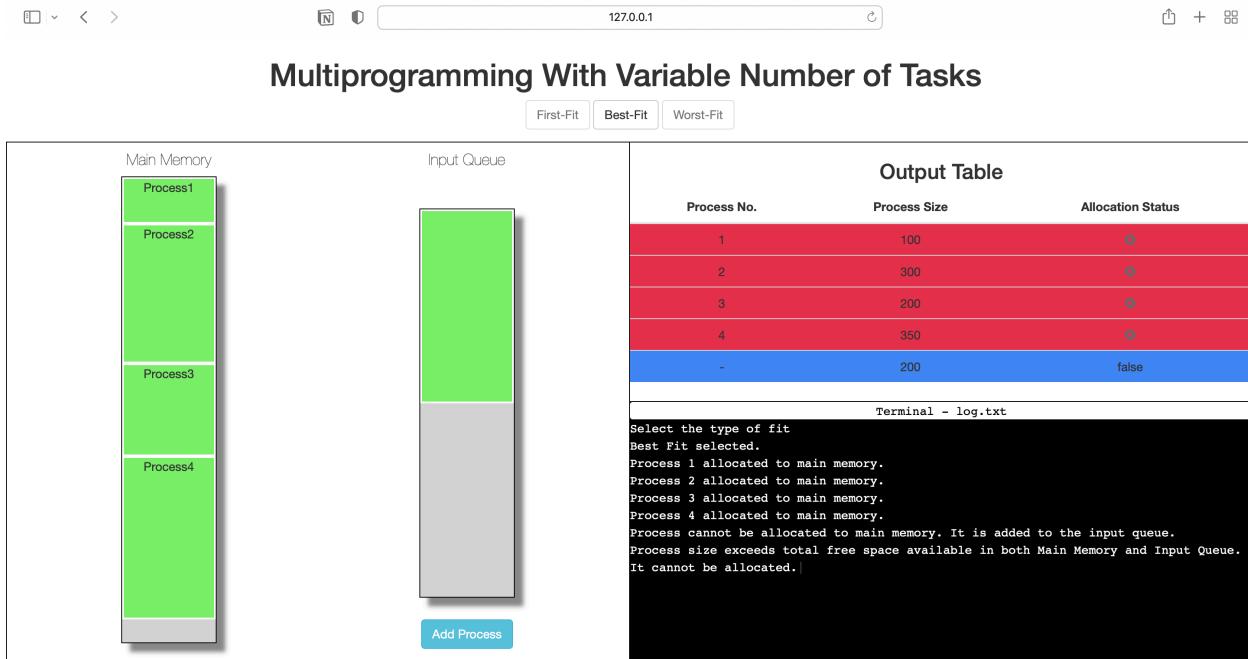

## MVT

This is an example when **Total Main Memory** is 1000 and **Input queue size** is 2 but **process 3** is 800. Process 3 size exceeds total free space available in both Main Memory and Input Queue so it is not added to Input Queue. (*Ignore Allocation Status*)\*

This is an example when the **Total Main Memory** is 1000, **Input queue size** is 400 so when main memory is full but the process size doesn't exceed input queue size, it will be added to input queue. Otherwise, it cannot be allocated.

## I/O Management

[CMSC312-OS-Simulator / ossim / disk / utils.py](#)

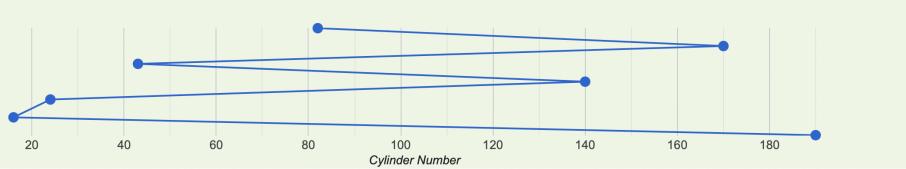

Disk scheduling is done by operating system to schedule I/O requests arriving for the disk so disk scheduling is also known as I/O scheduling. I/O scheduling is important because multiple I/O requests may arrive by different processes and only one I/O request can be served at a time by the disk controller. Therefore, other I/O requests need to wait in the waiting queue and need to be scheduled.

The file system may reside entirely on a single disk, or it may spread out on a number of disks. Therefore, all processes that ask for disk I/O services are competing for access to the same physical disk or set of physical disks. All processes must do at least one burst of disk I/O initially load a program to run. Any given disk can perform only one access at a time. Thus if there are several processes requesting for an access, the operating system must establish some order for the service of requests.

I/O requests are managed by Devices Drivers in collaboration with some system program inside the I/O device. The request are served by OS using three simple segments: I/O traffic controller, I/O scheduler and I/O device handler. I/O device handler manages the I/O interrupts and scheduling algorithms. I/O handling algorithms are FCFS, SSTF, SCAN, LOOK, C-SCAN, and C-LOOK. I choose to implement SSTF and FCFS. SSTF is common and has a natural appeal because it increases performance over FCFS.

## Disk Scheduling

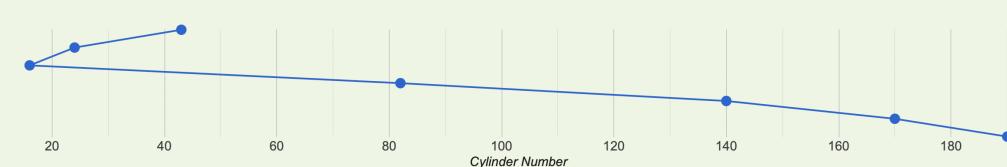

Current position: 50 Previous request: Requests (space separated): 82 170 43 140 24 16 190  
Number of Cylinders: 200 Select Algorithm: FCFS Send

Seek-Time : 642

## Disk Scheduling

Current position: 50 Previous request: Requests (space separated): 82 170 43 140 24 16 190  
Number of Cylinders: 200 Select Algorithm: SSTF Send

Seek-Time : 208

## Multi-threading and multi-CPU

Threading is just one of many ways concurrent programs can be built. I found there are several strategies in building concurrent program in Python and each of them is suitable in different scenarios. I personally think it is challenging to use Python for multithreading work. There is a thing called global interpreter lock (GIL) which prevents multiple threads of Python code from running simultaneously. Different from other language such as C++ or Java, Python multithreading module doesn't quite behave the way we would expect it. Below is the direction to check on the code. If you use VScode, you can do **Edit -> Find in files -> search for "Thread" or "threading"**, that way is easier to find the files that need to be checked.

venv > Lib > site-packages > asgiref > sync.py > ...

venv > Lib > site-packages > asgiref > current\_thread\_executor.py > \_WorkItem

venv > Lib > site-packages > django > test > runner.py > ...

# GIT Repository

## How to run the Operating System Simulator

You need to create a virtual environment to run this operating system simulator  
If you have not install python then you need to download latest version of the language.  
This is a guideline how to run the operating system on Mac

**Step 1:** Go to terminal. Check if the latest version of the language is install: `python3 --version`

**Step 2:** Install pip: `sudo easy_install pip`

**Step 3:** Install virtualenv for python: `sudo pip install virtualenv`

**Step 4:** Create a virtual environment:

- Navigate to Desktop
- Type: `virtualenv <choose a name for your virtualenv>` (Ex: Doraemon)

**Step 5:** Move the project folder (CMSC312-OS-Simulator) to the virtualenv you just created

**Step 6:** In terminal, navigate to Doraemon

**Step 7:** Activate the environment : `source bin/activate`

- To check if you are in the virtual environment, you will see `(Doraemon)` at the beginning

**Step 8:** Install the latest official version of Django: `sudo pip install django==3.0.1`

**Step 9:** Navigate to OS-Simulator/ossim

**Step 10:** Start the simulator: `python manage.py runserver`

**Step 11:** Copy the server address `http://127.0.0.1:8000` and run it in a browser

```
System check identified 10 issues (0 silenced).

You have 5 unapplied migration(s). Your project may not work properly until you apply
the migrations for app(s): admin, auth.
Run 'python manage.py migrate' to apply them.
October 31, 2021 - 13:40:07
Django version 3.2.8, using settings 'ossim.settings'
Starting development server at http://127.0.0.1:8000/
Quit the server with CONTROL-C.
